AMMonitor Photo Tools - Cheat Sheet (Part 1)

1. Do not use your web browser's "back" button. Use browser "refresh" button or the "Return to login" button to restart the app.
2. (tagger only) From left to right, these buttons will
 - Copy the tags from the previous image. Shortcut: SHIFT+C
 - Add a new tag (from selected options below). Shortcut: SHIFT+A
 - Open the photo at full size in a new tab.
3. Press the "+" plus sign to see image filter and settings options (see Cheat Sheet - Part 2)
4. Photo metadata is displayed in text above each image, including the file name, location, and date/time.
5. Photo-level tags pertain to the whole image (and not a particular taxon).
6. Taxon tags are annotations and annotags that pertain to a particular taxon. After selecting a taxon, all relevant annotags are displayed below. The "no-species" taxon is used to indicate the absence of a target species.
7. To create a bounding box, click on an image in the opposite corners to define the box. Unsaved bounding boxes have a yellow border, and saved boxes have a red border. To remove an un-saved bounding box, advance to the next/previous image.
8. These buttons, or the arrow keys → and ←, change photos. The "Save Labels" button (not visible in "viewer" mode) is clickable only when there are unsaved labels (annotations/annotags/mediatags/verifications).
9. Taxon Tags include all annotations and annotags associated with the image. Tags are filtered such that: in viewer mode, all tags are visible; in tagger mode, only tags made by the currently signed-in user are displayed; in verifier mode, only tags made by other users are displayed. When in viewer mode, model outputs can be included here by selecting this option from the image settings. When performing model verifications, only modeloutputs are displayed. A *verified* column is displayed when using the verifiers.
10. File Tags include all mediatags associated with the image. This table behaves similarly to the Taxon Tags table with respect to what is visible when using each of the different photo tools (i.e., viewer, tagger, verifiers).
11. Delete annotations/annotags/mediatags selected from the above tables (when in tagger mode).
12. These buttons can be used to add verifications that agree or disagree with either annotations/annotags/mediatags (Annotation Verifications), or with modeloutputs (Model Verifications). Verifications can be deleted with the "Clear" button. If no rows are selected to specify which tags to verify, the verification is applied to all tags. Keyboard shortcuts are the "plus" (+) key to "Agree" with a label or the "minus" key "-" to "Disagree" with a label.

AMMonitor Photo Tools - Cheat Sheet (Part 2)

1. Use the minus-sign “-” to hide the available/selected image filters and settings
2. Photo settings include:
 - Defining a “root” file path or URL for reading image files. If the filepath field for the photo is missing, this will be appended to the beginning of the filename when trying to render the image.
 - Adjusting the image size (in pixels)
 - (viewer mode only) Whether to show modeloutputs along with annotations/annotags/mediatags.
3. Images can be filtered by location, date range, and taxon. For the taxa filter, only labels made by the currently logged-in user will be displayed. There are also options for excluding images tagged (tagger mode only) or verified (verifier mode only) by the currently logged-in user (i.e., “Me”), or by anyone.
4. After selecting a location, the visits from that location will appear here. Selecting a visit will filter just images associated with the selected visit. The total number of images from each visit from the selected location are shown, along with the total number of images that the currently logged-in user has annotated.
5. Viewer settings can be used to reduce the number of database queries required by the image tagger. Cache size refers to the number of image files for which metadata is stored in memory at once. The auto-save rate (tagger and verifier modes only) controls how often the database is modified when changes are made. Set the auto-save rate to “1” to save automatically after each change. You can also randomize the photo order (by default, photos are displayed chronologically).
6. Model filters (model verifier mode only) allow a user to specify a model name and threshold value to filter by.
7. Go to a specific photo by file name (max. of 5,000 displayed).
8. When un-applied filters have been selected, a warning message will be displayed. Press the “Apply Filters” after changing filter settings to run a new query based on the selected options.
9. The number of images returned by the selected filters are shown here.

Note: AMMonitor allows setting defaults to be saved by using configuration files stored in the “settings” directory of an AMMonitor project. For more information on how to add default settings, and for video tutorials, run the AMMonitor tutorial:

```
learnr::run_tutorial("annotations", package = "AMMonitor")
```
